

Transition types.

External Transition.

→ You leave the current source state entirely.

→ It exits the source vertex / state.

Examples:

① → You are in kitchen (a state).

→ Event happens: Go to bedroom.

This is an External Transition.

② External transition has an exit behaviour.

→ (turn off the kitchen light before moving to ~~living~~ bedroom, this is exit behaviour)

③ Local Transition.

→ Within composite state.
Composite state always active. Only sub-state change inside.

④ Internal Transition.

→ Special local transition, where source and target are in the same state.

→ Event that the state can handle without ~~stop~~ disruption. (No entry / exit).

Example: event: turn up the volume.

Tv is in living room. I perform the action. But I don't exit or leave the living room.
